Advanced Machine Learning

Recommender Systems

Zdeněk Buk, Miroslav Čepek, **Rodrigo Da Silva Alves**, Vojtěch Rybář and Petr Šimánekc

March 14, 2024

Recommender Systems

- Recommenders recommend:
  - Items to users (most common).
  - Users to items.
  - Items to items.
  - Users to users.
- Items can be movies, products, news, music, books, recipes, etc.

Working in pairs: try to find one example of each of the four recommender scenarios above.

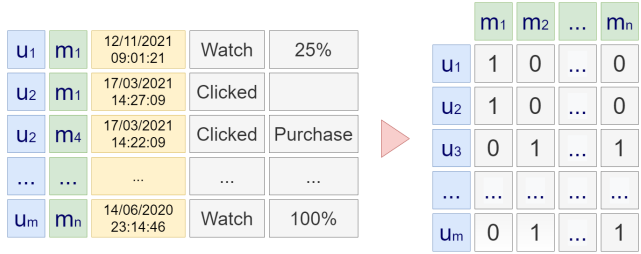
Recommender Systems

- WLOG, we will focus on recommending **users** relevant **items**.
  - Predictive modeling: predict the rating of item m by user u.
  - Retrieval modeling: learning a ranking system.
- Typically based on **past** **interactions** and/or **attributes** (from users and items).
- **Interactions**: normally modeled as an interaction matrix.
  - Explicit: a user rates a song with 4 stars on a scale from 0 to 5.
  - Implicit: a user watches 80% of a movie.
- **Attributes**: normally modeled as attribute matrices.
  - Users: gender, age, location, etc.
  - Items: text, video, meta-data, etc.

Modelling Interactions: Explicit feedback

	m_1	m_2	...	m_n
u_1	?	2	...	3
u_2	5	1	...	?
u_3	?	3	...	1
...	...	...	...	...
u_m	4	4	...	?

Modelling Interactions: Implicit feedback



u_1	m_1	12/11/2021 09:01:21	Watch	25%
u_2	m_1	17/03/2021 14:27:09	Clicked	
u_2	m_4	17/03/2021 14:22:09	Clicked	Purchase
...	...	...	...	...
u_m	m_n	14/06/2020 23:14:46	Watch	100%

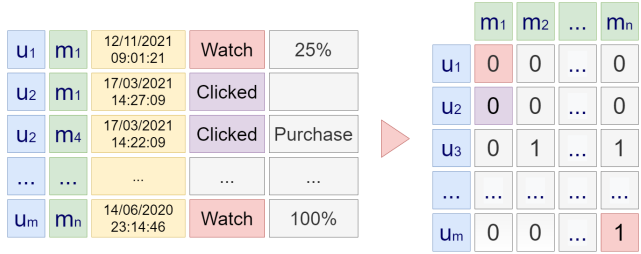
	m_1	m_2	...	m_n
u_1	1	0	...	0
u_2	1	0	...	0
u_3	0	1	...	1
...	...	...	...	...
u_m	0	1	...	1

From explicit to implicit feedback

	m_1	m_2	...	m_n
u_1	?	2	...	3
u_2	5	1	...	?
u_3	?	3	...	1
...	...	...	...	...
u_m	4	4	...	?

	m_1	m_2	...	m_n
u_1	?	0	...	0
u_2	1	0	...	?
u_3	?	0	...	0
...	...	...	...	...
u_m	1	1	...	?

From implicit to explicit feedback



Modelling Attributes

	Color	Price	Category
m_1	Black	24936	Chair
m_2	Red and White	24944	Chair
m_3	Red and White	1299	T-Shirt
m_4	Black	1104	Chair

Personalized Machine Learning

- Personalization *is not* a simple regression or classification problem.
- A personalized model implies that if the user has different interactions (or attributes), the recommendation should be different.
- Suppose the vector a_u (a_m) are attribute vectors of user u (item m).
- We can use linear regression to predict how user u will like item m:

$$r_{um} = \omega^\top \times \begin{bmatrix} a_u \\ a_m \end{bmatrix}$$

- Is linear regression a personalized model for recommenders? **No!**

Recommendation Algorithms

Collaborative Filtering

Day One: Joe and Julia independently read an article on police brutality

Day Two: Joe reads an article about deforestation, and then Julia is recommended the deforestation article

Content-Based Filtering

Day One: Julia watches a Drama

Day Two: Dramas are recommended

Recommender as a Matrix

- As we saw, we can model recommenders as matrices.
- The ratings can be stored in a **ranking matrix** R of dimension $m \times n$ with elements from $\mathbb{R} \cup \{?\}$.
- An example of a rating matrix for $m = 4$ users and $n = 6$ items can be read as:

$$R = \begin{pmatrix} 1 & ? & ? & 2 & ? & 1 \\ ? & 2 & 3 & ? & 2 & 1 \\ 1 & 5 & 5 & ? & ? & 5 \\ ? & ? & 2 & ? & ? & 3 \end{pmatrix}.$$

  This means, for example, that user u_1 ranked items i_1 and i_6 with 1 star, item i_4 with 2 stars, and had no interactions with items i_2, i_3, and i_5.

- **Our goal is to predict the unknown ratings** $r_{u,i} = ?$ using the knowledge of the known ratings $r_{u,i} \neq ?$.

Idea of Matrix Factorization

- By **matrix factorization** we usually mean expressing a given matrix R as a matrix product of two (or more) matrices with some **non-trivial properties**. For example:

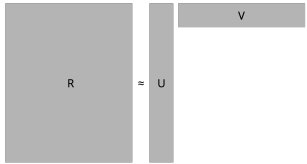
$$R = UV^\top$$

- These factorizations are a cornerstone of many algorithms and methods or are used to reach more numerically stable computations.

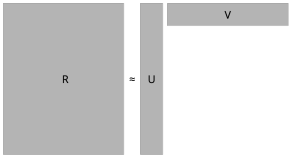
Do we need to know all the entries of a matrix R to factorize it, for example $R = UV^\top$?

Intuition Behind Matrix Factorization

- As for recommendation systems, the inspiration mainly comes from Singular Value Decomposition (SVD) as it can be used for constructing **latent features** or, in other words, **dimensionality reduction** using projections to a lower-dimensional space.
- The very basic idea of the **lower-dimensional** approximation of an input matrix R of dimension $m \times n$ is based on this fundamental fact from linear algebra: Multiplying matrices U of dimension $m \times d$ and V of dimension $d \times n$, we get a matrix of dimension $m \times n$. This is true for any **positive** integer d.
- And this is the idea: Given a rating matrix R, find **lower-dimensional** matrices U and V so that the known elements of R are well approximated by the matrix $\mathbf{UV}^\top$.



Matrix Factorization for Recommenders



- Let us denote:
  - The i-th row of U as u_i; the number of rows of U equals the number of users m.
  - The j-th column of V as v_j; the number of columns of V equals the number of items n.
  - Ω as the subset of $m \times n$ of user-item pairs (i,j) such that $r_{i,j}$ is known, i.e., $r_{i,j} \neq ?$.
- The approximation of $r_{i,j}$ is given by the number $u_i^T v_j$, i.e., by the dot product of the two d-dimensional vectors.

Optmization Problem

- The **error of approximation** is usually measured by the squared residual:

$$(r_{i,j} - u_i^T v_j)^2.$$

- Hence, the matrices U and V are obtained by solving the optimization task:

$$\text{argmin}_{\mathbf{U},\mathbf{V}} \sum_{(i,j)\in\Omega} (r_{i,j} - u_i^T v_j)^2 + \lambda(\sum_x ||u_x||^2 + \sum_y ||v_y||^2).$$

Sparsity and Prediction

- The matrices U and V are optimized only by considering the known entries of R, which are usually only a minority of entries.
- For example, in the Netflix Prize in 2006, there were $n = 17K$ movies and $m = 500K$ users, meaning that the matrix R had $8500M$ entries. But only $100M$ were given by Netflix!
- Still, the result of the matrix multiplication $UV^\top$ is a matrix having the same dimensions as R **with all entries known**!
- The unknown rating $r_{i,j} = ?$ is estimated as $\hat{r}_{i,j} = u_i^T v_j$.

Example

- Consider our toy example matrix from above:

$$R = \begin{pmatrix} 1 & ? & ? & 2 & ? & 1 \\ ? & 2 & 3 & ? & 2 & 1 \\ 1 & 5 & 5 & ? & ? & 5 \\ ? & ? & 2 & ? & ? & 3 \end{pmatrix}.$$

- Assume that we chose the hyperparameter $d = 2$, i.e., we look for approximation matrices U and V with dimensions 4×2 and 2×6, respectively.
- Let us pretend that the matrices resulting from the optimization are

$$U = \begin{pmatrix} 0.3 & 0.7 \\ 0.3 & 0.5 \\ 0.2 & 0.4 \\ 0.2 & 0.1 \end{pmatrix} \quad \text{and} \quad V^\top = \begin{pmatrix} 1 & 10 & 11 & 10 & 4 & 20 \\ 1 & -1 & -2 & -1 & 1 & -4 \end{pmatrix}.$$

Example

- The resulting approximation is

$$\mathbf{UV}^\top = \begin{pmatrix} 0.3 & 0.7 \\ 0.3 & 0.5 \\ 0.2 & 0.4 \\ 0.2 & 0.1 \end{pmatrix} \begin{pmatrix} 1 & 10 & 11 & 10 & 4 & 20 \\ 1 & -1 & -2 & -1 & 1 & -4 \end{pmatrix} =$$

$$= \begin{pmatrix} 1 & 2.3 & 1.9 & 2.3 & 1.9 & 3.2 \\ 0.8 & 2.5 & 2.3 & 2.5 & 1.7 & 4 \\ 0.6 & 1.6 & 1.4 & 1.6 & 1.2 & 2.4 \\ 0.3 & 1.9 & 2 & 1.9 & 0.9 & 3.6 \end{pmatrix},$$

  where the red numbers are the desired predictions

- E.g. the 3rd user predicted rating of the 4th item is $\hat{r}_{3,4} = 1.6$.

Supervised Learning Task

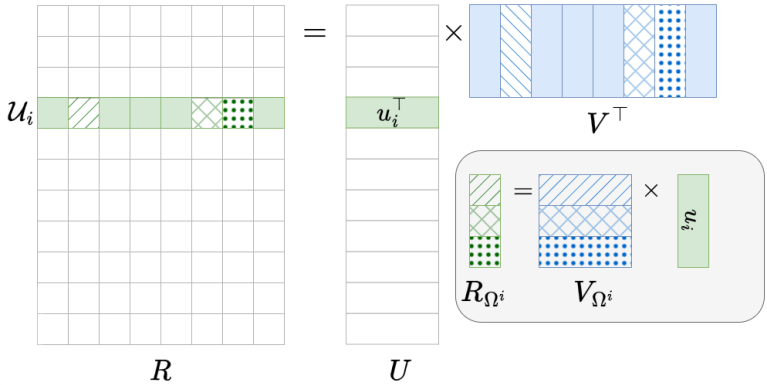
- The learning parameters: $U \in \mathbb{R}^{m \times d}$ and $V \in \mathbb{R}^{n \times d}$
- The hyperparameters:
  - the regularization constant $\lambda > 0$,
  - the matrix dimension d, which is a positive integer (significantly smaller than $\min\{m, n\}$).
- These hyperparameters can be tuned in the usual way via cross-validation.
- Therefore, we would like to learn U and V, given d and λ, by minimizing the following objective function:

$$\operatorname{argmin}_{\mathbf{U},\mathbf{V}} \sum_{(i,j)\in\Omega} (r_{i,j} - u_i^T v_j)^2 + \lambda \left(\sum_x ||u_x||^2 + \sum_y ||v_y||^2 \right).$$

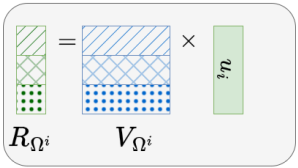
Alternating Least Squares (ALS)

- The idea of ALS is to fix alternately the matrix U and V.
  - The non-fixed matrix is then considered a learning variable and is subject to minimization.
- With **one of the matrices fixed**, the optimization problem becomes convex and very similar to the linear regression problem.
- Let's try to understand how the mechanism works.

Alternating least squares (ALS)



Alternating least squares (ALS)



- Then we have the following optimization problem

$$\min_{u_i} ||R_{\Omega^i} - u_i{}^\top V_{\Omega^i}\top||^2 + \lambda||u_i||^2$$

- Convex problem with closed-form

$$\hat{u}_i = (V_{\Omega^i} V_{\Omega^i}\top + \lambda I)^{-1} V_{\Omega^i}^\top R_{\Omega^i}$$

Alternating least squares (ALS)

Randomly initialize U and V

- **WHILE** does not converge
  - $\forall i \in \mathcal{U}$, $\min_{u_i} ||R_{\Omega^i} - u_i{}^\top V_{\Omega^i}\top||^2 + \lambda||u_i||^2$
  - $\forall j \in \mathcal{I}$, $\min_{v_j} ||R_{\Omega^j} - v_j{}^\top U_{\Omega^j}\top||^2 + \lambda||v_j||^2$

Matrix Factorization for Implicit Feedback

- In real-world applications, we often observe more implicit feedback than explicit feedback.
- In fact, explicit feedback is sometimes considered implicit.
- Suppose user i watched 35% of movie A and 85% of movie B.

Does this mean that the user likes A more than B? If so, does it mean that the user likes A more than twice as much as B?

- The method we learned so far is more appropriate for explicit feedback. **Why?**

Modelling Implicit Feedback

- Let's understand a more appropriate method for implicit feedback.
- Assume the binary interaction matrix P:

$$P = \begin{pmatrix} 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 \\ 1 & 1 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 \end{pmatrix}.$$

- That is, if user-i interacts with item-j, then $P_{ij} = 1$, otherwise $P_{ij} = 0$.
- Now let C be a matrix of confidence regarding the interaction:

$$C = \begin{pmatrix} 0.85 & 0 & 0 & 0.34 & 0 & 0.98 \\ 0 & 0.37 & 0.10 & 0 & 0.63 & 0.01 \\ 0.45 & 0.42 & 0.43 & 0 & 0 & 0.23 \\ 0 & 0 & 0.26 & 0 & 0 & 0.88 \end{pmatrix}.$$

Collaborative Filtering for Implicit Feedback

- Then we propose the following optimization problem:

$$\min_{U,V} \sum_{i,j} C_{ij}(P_{ij} - u_i^\top v_j)^2 + \lambda||u_i||^2 + \lambda||v_j||^2$$

- Two main differences from the previous MF method:
  - We need to account for the varying confidence levels.
  - Optimization should account for all possible i, j pairs, rather than only those corresponding to observed data.
- We can use gradient descent to solve it.
- And ALS? By fixing V, can we find u_i?

Closed Form

- Assume V being fixed and let's find u_i.
- Then we need to minimize the following loss:

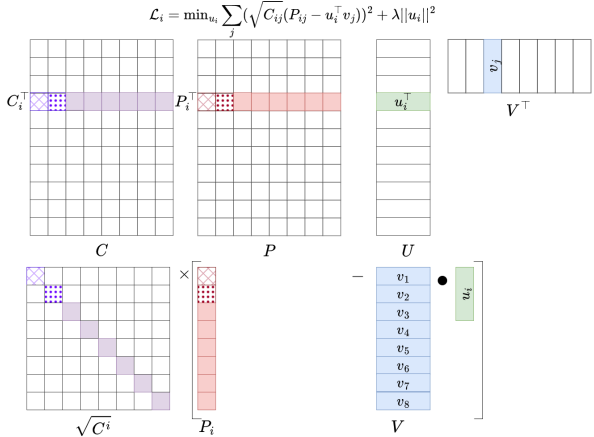
$$\mathcal{L}_i = \min_{u_i} \sum_j C_{ij}(P_{ij} - u_i^\top v_j)^2 + \lambda ||u_i||^2$$

That is the same as:

$$\mathcal{L}_i = \min_{u_i} \sum_j (\sqrt{C_{ij}}(P_{ij} - u_i^\top v_j))^2 + \lambda ||u_i||^2$$

Exercise: Find the closed form.

Alternating Least Squares (ALS)



Closed Form

- Therefore is the same of solving:

$$\mathcal{L}_i = ||\sqrt{C^i}P_i - \sqrt{C^i}Vu_i||^2 + \lambda + ||u_i||^2$$

- Taking the derivative

$$\nabla u_i = -2(\sqrt{C^i}V)^\top(\sqrt{C^i}P_i - \sqrt{C^i}Vu_i) + 2\lambda u_i$$

- Remind if D is diagonal $D = \sqrt{D} \times \sqrt{D}$ is trivial and $D = D^\top$
- Therefore, with just some algebraic derivations

$$u_i = (V^\top C^i V + \lambda I)^{-1} V^\top C^i P_i$$

Obrigado :) - Faculty of Information Technology
